To investigate ontogenetic changes in sleep organization, we studied daily amounts and distribution of sleep during the first posteclosion night in the desert grasshopper *Schistocerca gregaria*. Nocturnal (active) sleep occurred in a single prolonged bout, interrupted by periods of waking and of passive sleep. The daily average duration of sleep was relatively stable during the first post-eclosion night, whereas the hourly pattern of sleep changed markedly from one night to the next. The cumulative amounts of sleep were independent of the time of day, suggesting a similar influence of time of day on both the duration and the amount of sleep. However, an endogenous circadian clock of similar periodicity to that previously described in *S. gregaria* was found to entrain the daily and hourly patterns of sleep. Slow-wave sleep (stages 3 and 4) was observed only during the first hour after lights-off. This

time course of sleep is significantly different from that found in most insects. This study is, therefore, the first to report sleep organization in a noninsect hymenopteran, and it indicates a developmental decrease in the amount of slow-wave sleep that is characteristic of the juvenile stage in *S. gregaria*.
